This paper is very interesting since it highlights the eye injuries that can occur during or after COVID 19. However, it seems that the authors found too few cases, so as to reach to conclusions such as "This group of patients appears to be distinct from the group that presents with retinal vascular occlusion" or "This group of patients may benefit from primary steroid treatment as opposed to anticoagulant treatment as described for vascular occlusions". The authors should recommend studies with a larger number of patients and with long-term observation to corroborate this assertion.
