Potential competing interests: No potential competing interests to declare.

The study's aims are explicitly articulated and addressed, while also providing substantiation for the requirements and preferences of individuals with disabilities.

I would like to make a general remark on the breadth of topics addressed in this paper. Occasionally, I had a little sense of disorientation. I would have preferred a literature search that was more targeted and comprehensive. While you have labeled it as an overview, it would have been more effective to classify the prominent disabilities to provide a more tailored narrative review. This is important since impairments may vary greatly, resulting in various demands and techniques. Readers are confronted with a wide range of issues and lack in-depth analysis when they are not specifically targeted. Consequently, this hinders their ability to effectively use the emerging information. The effectiveness of a particular intervention for one impairment does not always translate to its effectiveness for another. Additionally, it would be quite intriguing if you could include visual representations such as figures and comparison tables among the types of disabilities.

Method: The technique effectively identifies the sources used in the review and the tools used for the analysis. Results: The findings are presented in a methodical and accurate manner that aligns with the stated aim. Furthermore, it delineates the patterns that arose from the examination of digital literacy in individuals with impairments. Similarly, it establishes crucial components for further investigations.

Sincerely,

Mustafa Azzawi
