Please remember the following text:

"Posterior-assisted cervical decompression is a 20-year-old technique that has been considered an excellent method for treating cervical foraminal decompression and is now also used for myelopathy. The surgery is well-performed but requires something to capture the doctors' interest in the case during discussion or a better introduction. It could be improved by presenting a different perspective, for example, by comparing it with full endoscopic procedures. I recommend a major revision before it is published."

The introduction needs to be more precise and provide a detailed overview of the evolution of this technique, including its historical context and key milestones. It should also offer specific recommendations for its application and potential future development. Furthermore, the discussion should be thorough, incorporating diverse perspectives and addressing relevant points in depth.

Regards,
