Dear Authors,

I was pleased to review the paper entitled "Bisphosphonate-Related Osteonecrosis of the Jaws Treated with Platelet-Rich Plasma: Preliminary Results from a Case Series".

The topic is very interesting, because, in recent years, the use of plasma rich in growth factors technology has shown successful results in many regenerative medical techniques and represent an important step for the orthopedic treatment.

However, this work doesn't confirm the ability of a platelet-rich plasma preparation BPFC to favor the healing process of patients affected by BRONJ.

As regards the introduction, the sections are well described, but in materials and methods, there is no a control group.

In result, there is no statistical analysis.

So the discussion and conclusions, are not balanced and well supported by statistic.

As last tip, i would have done a multicentre study.

Dear Editor, the scientific work is very interesting but it must be modified and improved.
