This study is very interesting as it is dealing with a very important clinical issue which is customized treatment with antiresorptive drugs in patients with bone metastases which is usually a prolonged treatment with unclear clinical guidelines. It is aiming to present experts' consensus regarding this issue which is needed for clinical practice as the current evidence about this issue is still insufficient. More details about this consensus and the methodology of collecting their opinions are required. In addition, some information need to be supported by evidence by adding relevant citations (for example to support that certain side effects are more in one type of ARDs than another).
