The article is interesting, especially for validating an instrument that health personnel demand. however, it would help to improve the objective by noting the various methods used, or by specifying that only confirmatory factor analysis was done. likewise, it should be included in the design that the study is instrumental since the instrument will be validated. When they indicate the instrument used, they should indicate the results of the exploratory factor analysis presented in the questionnaire or indicate why they are not considered. In my opinion, before using confirmatory factor analysis, the instrument should be explored to establish factor reduction and then confirm the model. Finally, the sample should be expanded for future research.
