# Humero-radial synostosis

INSERM

## Source

INSERM. (1999). *Orphanet: an online rare disease and orphan drug data base. Humero-radial synostosis. ORPHA:3265*

Humero-radial synostosis is a rare, genetic, congenital joint formation defect disorder characterized by uni- or bilateral fusion of the humerus and radius bones at the elbow level, with or without associated ulnar and carpal/metacarpal deficiency, leading to loss of elbow motion and, in many cases, functional arm incapacity. Bowing of radius may be additionally present.
