

Review of: "Case Report: Pott's Puffy Tumor, But Without The Tumor"

Irina Grigorieva

Potential competing interests: The author(s) declared that no potential competing interests exist.

The authors have presented a case report of a rare clinical entity with possible serious complications - Pott's Puffy Tumor. The incidence of the discussed condition in women is rare. The authors' management and surgical intervention had good recovery results without complications in a 3 month follow-up period.

The case report is worth publishing.

I would like to mention the attractive title of the article and underline some important missed details.

1. It is relevant to describe the previous and current use of antibiotics, since the "non-selective antibiotic treatment " was the possible cause of disease development.
2. It is not clear what was first, trauma or sinusitis? Is it possible to show CT-scans after trauma? Post-traumatic sinusitis with sinus fluid, which is often missed, may lead to complications. In fact, the history of clinical events helps us to understand the possibility of non-treated post-traumatic sinusitis.
3. It's better to choose only two or three enlarged CT-scans and mark them properly according figure legend.
4. Also it could be important to mention laboratory workup with blood cell count, comprehensive metabolic panel, erythrocyte sedimentation rate, and C-reactive protein.
5. Considering the etiopathogenesis it would be interesting to discuss the differential diagnosis and possible morphological anomalies.
