Multiple symmetric lipomatosis

INSERM

Source

INSERM. (1999). *Orphanet: an online rare disease and orphan drug data base. Multiple symmetric lipomatosis. ORPHA:2398*

Multiple symmetric lipomatosis (MSL) is a rare subcutaneous tissue disease characterized by growth of symmetric non-encapsulated masses of adipose tissue mostly around the face and neck with variable clinical repercussions (e.g. reduced neck mobility, compression of respiratory structures).
