# Extensor tendons of finger anomalies

INSERM

## Source

INSERM. (1999). *Orphanet: an online rare disease and orphan drug data base. Extensor tendons of finger anomalies. ORPHA:3294*

Extensor tendons of finger anomalies is a rare, genetic, congenital limb malformation characterized by bilateral anomalous attachment of the extensor tendons of the four ulnar fingers. Attachment occurs to the medial and lateral aspects of the middle phalanges leading to constant flexion in the midphalangeal joints and inability to extend the fingers. There have been no further descriptions in the literature since 1980.
