Potential competing interests: No potential competing interests to declare.

This study effectively explores the healthcare needs and utilisation patterns of refugee children in Turkey, showcasing a well-crafted writing style and informative content. The introduction is adept, providing a solid background and justification for the research. The methods section is clearly articulated and suitable for a retrospective review of medical records, though offering more explicit details on the data analysis plan, including specific statistical tests, would enhance clarity.

The results section is commendable, presenting main findings in an organised manner with useful summary tables and a figure. To enhance readability, incorporating more subheadings could help break up the text and emphasise key takeaways. In the discussion, establishing a clearer link between the main findings and existing literature would enhance the overall coherence of the study. It's important to explicitly identify where the results align with or diverge from previous research.

Furthermore, expanding on the implications of the findings for clinical practice and health policy is crucial. Providing specific recommendations based on the data would strengthen the study's practical relevance. Addressing generalisability and limitations, particularly any biases inherent in the retrospective chart review design, would contribute to a more comprehensive interpretation of the results.

The conclusion could benefit from expansion to succinctly summarise key implications and outline potential next steps arising from the research. By addressing these points, the study can further strengthen its contribution to the understanding of healthcare for refugee children and guide future research and policy initiatives.
