This research note emphasizes the importance of various treatment options that could potentially work to reduce the complications of dengue. Dengue is endemic to Mexico and some other regions of the world and as such, more preventive measures are needed. The authors started off by listing few everyday consumable food items that are rich in polyphenol flavonoids and techniques to reduce the population of the mosquitos' causing dengue. Other treatments options for dengue were also discussed in detail with the final conclusion that further research is needed. This is an important research note that will help researchers studying the disease of dengue to hypothesize various research questions.
