Potential competing interests: No potential competing interests to declare.

Although epidemiological data show that the prevalence of fibromyalgia syndrome is still low (The global prevalence of FM, in 26 studies worldwide, is 2.7%*), this article is quite interesting and useful for the scientific community, medical practitioners and public health (for the benefit of anticipation and prevention).). Because the prevalence is low, it is understandable if researchers still use very few research samples with eligibility criteria as respondents that are not too strict. This article has been written based on scientific research, with very good quality writing. In order for research results on fibromyalgia and its relationship with Hypermobility and Neurodivergence Extends to Families to be generalized to the general population, I suggest that similar studies be carried out in various hospitals both inside and outside Middlesbrough.
