Dear authors,

The article is very interesting and well presented.

It would be important if the results obtained could be confirmed in other groups performing rapid ascent, as this would increase the number of subjects in the study and allow for greater confirmation of the results obtained.

On the other hand, and as an idea, perhaps it would be useful to know the initial haemoglobin levels of the different members of the study, as anaemia could also affect the response to ascent.

In any case, congratulations to the authors, as I believe that this type of work is very useful and not easy to carry out, and the results obtained are of great help to other groups.

Best regards,
