

# Review of: "Immediate test-retest reliabilities of intention to quit smoking measures in current adult smokers"

Aldo Pezzuto

Potential competing interests: No potential competing interests to declare.

It is very interesting study

Since it is an evaluation study of the intention to quit

it would be important if possible, to determine the variables and comorbidities affecting the outcomes and the probability to quit. Is it possible to determine the pack-years index and Fagestrom test value?

There are some conditions that are associated with a higher quit probability.

I suggest to include a reference about smoking cessation expectancies of patients undergoing cessation program useful for discussion.
